

NMix

Parametrisation

The N-Mixture distribution is a Poisson mixture of the Binomials, as

$$\text{Prob}(y) = \sum_{n=y}^{\infty} \binom{n}{y} p^n (1-p)^{n-y} \times \frac{\lambda^n}{n!} \exp(-\lambda)$$

for responses $y = 0, 1, 2, \dots, n$, where n is Poisson number of trials, and p is probability of success. Replicated reponses y_1, y_2, \dots, y_r , are iid from the Binomial, given (a common) n from the Poisson,

$$\text{Prob}(y_1, \dots, y_r) = \sum_{n=\max\{y_1, \dots, y_r\}}^{\infty} \left\{ \prod_{i=1}^r \binom{n}{y_i} p^n (1-p)^{n-y_i} \right\} \times \frac{\lambda^n}{n!} \exp(-\lambda)$$

Link-function

The probability p is linked to the linear predictor by

$$p(\eta) = \frac{\exp(\eta)}{1 + \exp(\eta)}$$

for the default logit link, while λ depends on fixed covariates

$$\log(\lambda) = \sum_{j=1}^m \beta_j x_j$$

with one vector of covariates for each observation. m can be maximum 5 and minimum 1.

Hyperparameters

The parameters $\beta_1, \beta_2, \dots, \beta_m$

Specification

- family = nmix
- Required arguments: the response Y and covariates X as `inla.mdata(Y, X [, additional.covariates])`

The response is a matrix where each row are replicates, where responses that are NA's are ignored. The covariates is one or many vectors, matrices or data.frames. Each row of the covariates $(x_{i1}, x_{i2}, \dots, x_{im})$ defines the covariates used for the i 'th response(s) (the i 'th row of Y). Note that $\beta_{m+1}, \dots, \beta_5$ are fixed to zero.

Example

In the following example we estimate the parameters in a simulated example with binomial responses.

```
nrep = 10
n = 50
y = matrix(NA, n, nrep)
x = c()
xx = c()
h = 0.01

for(i in 1:n) {
  local.x = runif(1) - 0.5
  lambda = exp(2 + local.x)
  local.xx = runif(1) - 0.5
  intercept = 1
  eta = intercept + local.xx
  p = exp(eta)/(exp(eta) + 1)
  nr = sample(1:nrep, 1) ## sample number of replications
  N = rpois(1, lambda)
  y[i, 1:nr] = rbinom(nr, size = N, prob = p)
  x = c(x, local.x)
  xx = c(xx, local.xx)
}

Y = inla.mdata(y, 1, x)
r = inla(Y ~ -1 + offset(off) + xx,
        data = list(Y=Y, xx=xx, off=rep(intercept, n)),
        family = "nmix",
        control.fixed = list(prec.intercept=1, prec=1))
```
