The Kumaraswamy distribution

Parametrisation

The Kumaraswamy distribution is

$$f(y) = \alpha \beta y^{\alpha - 1} (1 - y^{\alpha})^{\beta - 1}$$

for 0 < y < 1 and $\alpha, \beta > 0$. The cumulative distribution function is

$$F(y) = 1 - (1 - y^{\alpha})^{\beta}$$
.

The parametrisation is given in terms of the quantile function

$$\kappa(q) = \left(1 - (1 - q)^{1/\beta}\right)^{1/\alpha}$$

and the precision parameter ϕ ,

$$\phi(q) = -\ln\left(1 - (1 - q)^{1/\beta}\right)$$

for fixed value of 0 < q < 1.

Link-function

The quantile κ to the linear predictor by

$$logit(\kappa) = \eta$$

using the default logit link-function.

Hyperparameters

The hyperparameter is

$$\phi = \exp(S\theta)$$

and the prior is defined on θ . The constant S currently set to 0.1 to avoid numerical instabilities in the optimization, since small changes of α can make a huge difference.

Specification

- family = qkumar
- Required arguments: y and the quantile q.

The quantile is given as control.family=list(control.link = list(quantile=q)).
