The Beta-distribution

Parametrisation

The Beta-distribution has the following density

$$\pi(y) = \frac{1}{B(a,b)} y^{a-1} (1-y)^{b-1}, \qquad 0 < y < 1, \quad a > 0, \quad b > 0$$

where B(a, b) is the Beta-function

$$B(a,b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}$$

and $\Gamma(x)$ is the Gamma-function. The (re-)parameterisation used is

$$\mu = \frac{a}{a+b}, \qquad 0 < \mu < 1$$

and

$$\phi = a + b, \qquad \phi > 0,$$

as it makes

$$E(y) = \mu$$
 and $Var(y) = \frac{\mu(1-\mu)}{1+\phi}$.

The parameter ϕ is known as the *precision parameter*, since for fixed μ , the larger ϕ the smaller the variance of y. The parameters $\{a,b\}$ are given as $\{\mu,\phi\}$ as follows,

$$a = \mu \phi$$
 and $b = -\mu \phi + \phi$.

Link-function

The linear predictor η is linked to the mean μ using a default logit-link

$$\mu = \frac{\exp(\eta)}{1 + \exp(\eta)}.$$

Hyperparameter

The hyperparameter is the precision parameter ϕ , which is represented as

$$\phi = \exp(\theta)$$

and the prior is defined on θ .

Specification

- family = beta
- Required arguments: y.

Hyperparameter spesification and default values

hyper

theta

name precision parameter
short.name phi

```
initial 2.30258509299405
          fixed FALSE
          prior loggamma
          param 1 0.1
          to.theta function(x) log(x)
          from.theta function(x) exp(x)
survival FALSE
discrete FALSE
link default logit probit cloglog
\mathbf{pdf} beta
Example
In the following example we estimate the parameters in a simulated example.
## the precision parameter in the beta distribution
phi = 5
## generate simulated data
n = 1000
z = rnorm(n, sd=0.2)
eta = 1 + z
mu = exp(eta)/(1+exp(eta))
a = mu * phi
b = -mu * phi + phi
y = rbeta(n, a, b)
## estimate the model
formula = y \sim 1 + z
r = inla(formula, data = data.frame(y, z), family = "beta")
summary(r)
```

Notes

None.
