### The Beta-distribution

### Parametrisation

The Beta-distribution has the following density

$$\pi(y) = \frac{1}{B(a,b)} y^{a-1} (1-y)^{b-1}, \qquad 0 < y < 1, \quad a > 0, \quad b > 0$$

where B(a, b) is the Beta-function

$$B(a,b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}$$

and  $\Gamma(x)$  is the Gamma-function. The (re-)parameterisation used is

$$\mu = \frac{a}{a+b}, \qquad 0 < \mu < 1$$

and

$$\phi = a + b, \qquad \phi > 0,$$

as it makes

$$E(y) = \mu$$
 and  $Var(y) = \frac{\mu(1-\mu)}{1+\phi}$ .

The parameter  $\phi$  is known as the *precision parameter*, since for fixed  $\mu$ , the larger  $\phi$  the smaller the variance of y. The parameters  $\{a,b\}$  are given as  $\{\mu,\phi\}$  as follows,

$$a = \mu \phi$$
 and  $b = -\mu \phi + \phi$ .

### **Link-function**

The linear predictor  $\eta$  is linked to the mean  $\mu$  using a default logit-link

$$\mu = \frac{\exp(\eta)}{1 + \exp(\eta)}.$$

# Hyperparameter

The hyperparameter is the precision parameter  $\phi$ , which is represented as

$$\phi = \exp(\theta)$$

and the prior is defined on  $\theta$ .

# Specification

- family = beta
- Required arguments: y.

### Hyperparameter spesification and default values

## hyper

theta

hyperid 61001 name precision parameter

```
short.name phi
         initial 2.30258509299405
         fixed FALSE
         prior loggamma
         param 1 0.1

Example
In the following example we estimate the parameters in a simulated example.
## the precision parameter in the beta distribution
phi = 5
## generate simulated data
n = 1000
z = rnorm(n, sd=0.2)
eta = 1 + z
mu = exp(eta)/(1+exp(eta))
a = mu * phi
b = -mu * phi + phi
y = rbeta(n, a, b)
## estimate the model
formula = y \sim 1 + z
r = inla(formula, data = data.frame(y, z), family = "beta")
summary(r)
