The Classical Measurement Error (MEC) model

Parametrization

This is an implementation of the classical ME model for a fixed effect. It is best described by an example, let the model be

$$y = \beta x + \epsilon$$

where y is the response, β the effect of the true covariate x with zero mean Gaussian noise ϵ. The issue is that x is not observed directly, but only through w, where

$$w = x + u$$

where u is zero mean Gaussian noise. Even though this setup is possible to implement using basic features ("copy" and multiple likelihoods), we provide the following model which replaces the above,

$$y = \nu + \epsilon$$

where $\nu = \beta x$ has the correct distribution depending on various parameters: β has prior $\pi(\beta)$, x is apriori $\mathcal{N}(\mu_x I, \tau_x I)$, and $s \times \tau_u$ is the observation precision for x (i.e., $\mathrm{Prec}(u|x)$).[1] Here, s is a vector of fixed scalings.

Hyperparameters

This model has 4 hyperparameters, $\theta = (\theta_1, \theta_2, \theta_3, \theta_4)$ where θ_2, θ_3 and θ_4 are default set to be fixed (ie defined to be known). The values of θ_2, θ_3 and θ_4 are set to mimic a classical fixed effect, so they will always make sense. To achieve the ME model, please use the appropriate choices for (some of) these parameters!

The hyperparameter specification is as follows:

$$\theta_1 = \beta$$

and the prior is defined on θ_1,

$$\theta_2 = \log(\tau_u)$$

and the prior is defined on θ_2,

$$\theta_3 = \mu_x$$

and the prior is defined on θ_3,

$$\theta_4 = \log(\tau_x)$$

and the prior is defined on θ_4.

Specification

The MEC is specified inside the `f()` function as

```
f(w, [<weights>,] model="mec", hyper = <hyper>, scale = <s>)
```

The `w` are the observed values of the true but unknown covariates x, with the *assumption*, that if two or more elements of `w` are *identical*, then they refer to the *same* element in the true covariate x. The fixed scaling of the observational precision is given in argument `scale`. If the argument `scale` is not given, then s is set to 1.

---

[1]Note: The second argument in $\mathcal{N}(,)$ is the precision not the variance.

```

Notes

- `INLA` provide the posterior of ν and NOT x.

- The posterior of ν comes (default) in the order given by the sorted (from low to high) values of `w`. The entry `$ID` gives the mapping.

- The option `scale` defines the scaling in the same order as argument `values`. It is therefore adviced to also give argument `values` when `scale` is used to be sure that they are consistent.
