Intercept-slope model

Parametrization

The intercept-slope model is a convenient reimplementation of a commonly used construct, where

$$(a, b)$$

is bivariate Gaussian with a Wishart prior for the precision matrix[1], and various forms of

$$\gamma(a + bz), \tag{1}$$

where z is a covariate and γ is a (random) scaling, goes into the linear predictor. Replicates of (a, b) is indexed by *subject*, $i = 1, \ldots, n$, and the various scaling of Eq. 1 by *strata* $j = 1, \ldots, m$, leading to a model for (a subset of)

$$\left\{ \gamma_j(a_i + b_i z_{ij}), \quad i = 1, \ldots, n, \quad j = 1, \ldots, m \right\},$$

as not all combinations need to be present.

Hyperparameters

The hyperparameters are $(\theta_1, \theta_2, \theta_3)$ as in the model "iid2d" (related to the precisions of a and b, and their correlation), and $\theta_4 = \gamma_1, \ldots, \theta_{13} = \gamma_{10}$. Since m is defined in the input, only $\gamma_1, \ldots, \gamma_m$ are used. m is limited to $m \leq 10$. Note that γ_1 is by default **fixed** to 1, due to confounding issues.

Specification

The is specified as

```
f(idx, model="intslope", hyper = ...,
  precision = exp(14),
  args.intslope = list(subject=i, strata=j, covariate = z))
```

The defintion of the model is through the `args.intslope` argument, where `i` and `j` are factors/integers and `z` is numerical, all with same length N, say. The argument `idx`, index which row that is used, hence values of `idx` must take integer values in the interval 1 to N. The precision argument, defines the tiny small noise added to each $\gamma(a + bz)$ to avoid a singular joint model. The `subject` and `strata` argument, is converted internally as

```
subject = as.numerical(as.factor(subject))
strata  = as.numerical(as.factor(strata))
```

and the results is shown after this conversion.

Example

```
library(mvtnorm)
n = 300
idx = 1:n
nstrata = 3
strata = sample(1:nstrata, n, replace=TRUE)
nsubject = n %/% nstrata
subject = sample(1:nsubject, n, replace=TRUE)
z = rnorm(n)
gam = c(1, 1 + rnorm(nstrata-1, sd = 0.2))

rho = sqrt(3)/2
Sigma = matrix(c(1/1, NA, NA, 1/2), 2, 2)
Sigma[1,2] = Sigma[2,1] = rho*sqrt(Sigma[1,1]*Sigma[2,2])

ab = rmvnorm(nsubject, sigma=Sigma)
a = ab[,1]
b = ab[,2]
s = 0.01
y = numeric(n)
for(k in 1:n) {
    y[k] = gam[strata[k]] * (a[subject[k]] + z[k] * b[subject[k]]) +
            rnorm(1, s = 0.01)
}
r = inla(y ~ -1 + f(idx, model = "intslope",
                    args.intslope = list(subject = subject,
                                            strata = strata,
                                            covariates = z)),
        data = list(y = y,
                    idx = idx,
                    subject = subject,
                    strata = strata,
                    z = z),
        control.family = list(hyper = list(
                            prec = list(initial = log(1/s^2),
                                        fixed=TRUE))))
summary(r)
```

Notes

- With $n_s = \max(\text{subject})$, the internal storage of this model is

$$\left(\gamma_{j_1}(a_{i_1} + z_1 b_{i_1}), \ldots, \gamma_{j_N}(a_{i_N} + z_N b_{i_N}), a_1, \ldots, a_{n_s}, b_1, \ldots, b_{n_s}\right),$$

  i.e. a vector of length $N + 2n_s$.
